

### 30-Aug-2020: Welcome Video, and What is Machine Learning

- Machine learning: algorithms; supervised, unsupervised, reinforcement, recommender. In this course, also will learn best practices.

### 31-Aug-2020: Supervised Learning, and Unsupervised Learning

- Supervised learning: right answers are given
- Regression: predicts continuous variable output; Classification: predicts discrete values
- Classification can have  $1, \dots, N, \dots, \infty$  attributes. E.g. benignness/malignancy based on age, or age and tumor size, etc.
- Unsupervised learning a.k.a. clustering: Right answers aren't given. For example, news that links to different sources for the same topic.
- Cocktail party algorithm: separates two voices in a conversation, with two microphone recordings. Singular value decomposition is key to this algorithm.
- When learning machine learning, use Octave

### 1-Sep-2020: Model Representation, and Cost Function

- Training set notation:  $m$  is number of training examples,  $x$  are input examples, and  $y$  are the output variables. Together,  $(x, y)$  form a training example. Also denoted  $(x^{(i)}, y^{(i)})$ .
- In a linear regression,  $h_{\theta}(x) = \theta_0 + \theta_1 x \equiv h(x)$ .
- Cost function is

$$J(\theta_0, \theta_1) = \frac{1}{2m} \sum_{i=1}^m \left( h_{\theta}(x^{(i)}) - y^{(i)} \right)^2$$

- Want to minimize  $J$  w.r.t.  $\theta_0$  and  $\theta_1$ .

### 4-Sep-2020: Cost Function, Intuition I&II; Gradient Descent

- Intuition I; Let  $\theta_0 = 0$ , then  $\min_{\theta_1} J(\theta_1)$  is what we want
- Ex:  $h_{\theta}(x) = \theta_1 x$  and let  $(x, y) = \{(1, 1), (2, 2), (3, 3)\}$ .

$$J(\theta_1) = \frac{1}{2m} \sum_{i=1}^m \left( h_{\theta}(x^{(i)}) - y^{(i)} \right)^2$$

$$\rightarrow \text{If } \theta_1 = 0, h_{\theta}(x) \equiv 0$$

$$\begin{aligned} J(0) &= \frac{1}{2 \times 3} (1 + 4 + 9) \\ &= \frac{14}{6} \end{aligned}$$

- $J(\theta_1)$  is parabolic
- We want  $\min_{\theta} J(\theta)$ ; here,  $\theta_1 = 1$  satisfies this criterion
- Intuition II; Let  $\theta_0, \theta_1$  be free in  $J(\theta_0, \theta_1)$  and  $h_{\theta}(x)$ .
- $J(\theta_0, \theta_1)$  is a paraboloid
- Gradient Descent; Use gradient descent to find  $(\theta_0, \theta_1)$  that minimizes  $J(\theta_0, \theta_1)$ .
- Differing starting guesses can give different local minima.
- Gradient descent algorithm:

$$\theta_j := \theta_j - \alpha \frac{\partial}{\partial \theta_j} J(\theta_0, \theta_1) \quad \text{for } j = 1, 2$$

- Simultaneously update  $\theta_0, \theta_1$ ,  $\alpha$  is called the learning rate.
- Ex:  $\theta_0 = 1, \theta_2 = 2$  and  $\theta_j := \theta_j + \sqrt{\theta_0 \theta_1}$ .

$$\begin{aligned} \theta_0 &:= \theta_0 + \sqrt{\theta_0 \theta_1} \\ &= 1 + \sqrt{1 \times 2} \\ &= 1 + \sqrt{2} \end{aligned}$$

$$\begin{aligned} \theta_1 &= \theta_2 + \sqrt{\theta_0 \theta_1} \\ &= 2 + \sqrt{1 \times 2} \quad \text{note here that we used the old value of } \theta_0 \\ &= 2 + \sqrt{2} \end{aligned}$$

## 5-Sep-2020: Gradient Descent Intuition, Gradient Descent for Linear Regression

- Gradient Descent Intuition: For simplicity, assume  $\theta_0 = 0$
- One variable:  $\theta_1 := \theta_1 - \alpha \frac{d}{d\theta_1} J(\theta_1)$ ; Newton-Raphson
- If  $\alpha$  is too small, convergence may be very slow. If too large, it may miss the minimum.
- If  $\theta_1$  is already at a local minimum, g.d. leaves  $\theta_1$  unchanged since the derivative is zero.
- Gradient Descent for Linear Regression: We need derivatives

$$\frac{\partial}{\partial \theta_0} J(\theta_0, \theta_1) = \frac{1}{m} \sum_{i=1}^m (\theta_0 + \theta_1 x^{(i)} - y^{(i)})$$
$$\frac{\partial}{\partial \theta_1} J(\theta_0, \theta_1) = \frac{1}{m} \sum_{i=1}^m (\theta_0 + \theta_1 x^{(i)} - y^{(i)}) \times x^{(i)}$$

- So, gradient descent finds the new  $\theta$  variables as

$$\theta_0 := \theta_0 - \alpha \frac{1}{m} \sum_{i=1}^m (\theta_0 + \theta_1 x^{(i)} - y^{(i)})$$
$$\theta_1 := \theta_1 - \alpha \frac{1}{m} \sum_{i=1}^m (\theta_0 + \theta_1 x^{(i)} - y^{(i)}) \times x^{(i)}$$

- This is called “batch gradient descent”; batch implies looking at all the training examples. This is represented by the  $\sum_{i=1}^m$ .
- Quiz Linear Regression with One Variable: 2)  $m = \Delta y / \Delta x = (1 - 0.5) / (2 - 1) = 0.5 \implies y = 0.5x + b$ ; y-intercept is clearly zero since (0,0) is a data point.
- 3)  $h_\theta(x)$ ;  $\theta_0 = -1$ ,  $\theta_1 = 2$ ;  $h_\theta(6) = -1 + 2 \times 6 = 11$

## 9-Sep-2020: Linear Algebra Review

- Matrices and Vectors: Nothing new; in this course, index from 1.
- Addition and Scalar Multiplication: Nothing new
- Matrix Vector Multiplication: Nothing new;
- Ex: Let house sizes be {2104, 1416, 1534, 852}. Let the hypothesis be  $h_\theta(x) = -40 + 0.25x$ .

$$\begin{bmatrix} 1 & 2104 \\ 1 & 1416 \\ 1 & 1534 \\ 2 & 852 \end{bmatrix} \begin{bmatrix} -40 \\ 0.25 \end{bmatrix} = \begin{bmatrix} -40 \times 1 + 0.25 \times 2104 \\ -40 \times 1 + 0.25 \times 1416 \\ -40 \times 1 + 0.25 \times 1534 \\ -40 \times 1 + 0.25 \times 852 \end{bmatrix} = \begin{bmatrix} h_\theta(2104) \\ h_\theta(1416) \\ h_\theta(1534) \\ h_\theta(852) \end{bmatrix}$$

This essentially says data matrix  $\times$  parameters = prediction

- Best to do this with built-in linear algebra function in Octave/Python. You can do it manually in a for-loop, but it'll be really slow.
- Matrix Multiplication: Take the same example. Now we have three hypotheses:

$$h_\theta(x) = -40 + 0.25x$$

$$h_\theta(x) = 200 + 0.1x$$

$$h_\theta(x) = -150 + 0.4x$$

In matrix form, this becomes

$$\begin{bmatrix} 1 & 2104 \\ 1 & 1416 \\ 1 & 1534 \\ 2 & 852 \end{bmatrix} \begin{bmatrix} -40 & 200 & -150 \\ 0.25 & 0.1 & 0.4 \end{bmatrix} = \begin{bmatrix} 486 & 410 & 692 \\ 314 & 342 & 416 \\ 344 & 353 & 464 \\ 173 & 285 & 191 \end{bmatrix}$$

- Matrix Multiplication Properties: Not commutative.  $AB \neq BA$ . But it's associative.  $ABC = (AB)C = A(BC)$ .
- Identity matrix is  $I$  such that  $AI = IA = A$ .  $I = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$  in 2D.

- Inverse of  $A$  is  $A^{-1}$  such that  $AA^{-1} = A^{-1}A = I$ .
- Transpose of  $A$  is  $A^T$ . If  $B = A^T$ , then  $B_{ij} = A_{ji}$ .
- Quiz: 4)  $u = \begin{bmatrix} 3 \\ -5 \\ 4 \end{bmatrix}$ ,  $v = \begin{bmatrix} 1 \\ 2 \\ 5 \end{bmatrix}$ , then  $u^T v = \begin{bmatrix} 3 & -5 & 4 \end{bmatrix} \begin{bmatrix} 1 \\ 2 \\ 5 \end{bmatrix} = -3 + (-10) + 20 = 13$ .
